

Chapter 12

Connections on Manifolds

12.1 Connections on Manifolds

Given a manifold, M , in general, for any two points, $p, q \in M$, there is no “natural” isomorphism between the tangent spaces T_pM and T_qM .

Given a curve, $c: [0, 1] \rightarrow M$, on M as $c(t)$ moves on M , how does the tangent space, $T_{c(t)}M$ change as $c(t)$ moves?

If $M = \mathbb{R}^n$, then the spaces, $T_{c(t)}\mathbb{R}^n$, are canonically isomorphic to \mathbb{R}^n and any vector, $v \in T_{c(0)}\mathbb{R}^n \cong \mathbb{R}^n$, is simply moved along c by *parallel transport*, that is, at $c(t)$, the tangent vector, v , also belongs to $T_{c(t)}\mathbb{R}^n$.

However, if M is curved, for example, a sphere, then it is not obvious how to “parallel transport” a tangent vector at $c(0)$ along a curve c .

A way to achieve this is to define the notion of *parallel vector field* along a curve and this, in turn, can be defined in terms of the notion of *covariant derivative* of a vector field.

Assume for simplicity that M is a surface in \mathbb{R}^3 . Given any two vector fields, X and Y defined on some open subset, $U \subseteq \mathbb{R}^3$, for every $p \in U$, the *directional derivative, $D_X Y(p)$, of Y with respect to X* is defined by

$$D_X Y(p) = \lim_{t \rightarrow 0} \frac{Y(p + tX(p)) - Y(p)}{t}.$$

See Figure 12.1.

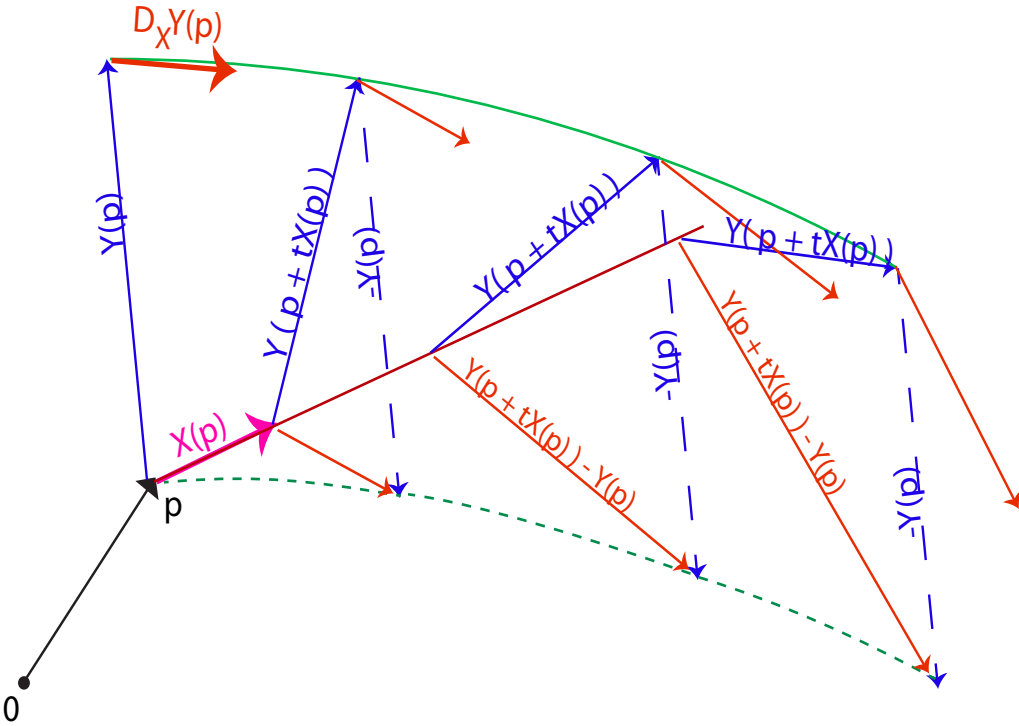

Figure 12.1: The directional derivative of the blue vector field $Y(p)$ in the direction of X .

Observe that the above is the directional derivative of the function $p \mapsto Y(p)$ as given in Definition 2.1, except that the direction vector $X(p)$ varies with p .

If $f: U \rightarrow \mathbb{R}$ is a differentiable function on U , for every $p \in U$, the *directional derivative*, $X[f](p)$ (or $X(f)(p)$), of f with respect to X is defined by

$$X[f](p) = \lim_{t \rightarrow 0} \frac{f(p + tX(p)) - f(p)}{t}.$$

We know that $X[f](p) = df_p(X(p))$.

It is easily shown that $D_X Y(p)$ is \mathbb{R} -bilinear in X and Y , is $C^\infty(U)$ -linear in X and satisfies the Leibniz derivation rule with respect to Y , that is:

Proposition 12.1. *The directional derivative of vector fields satisfies the following properties:*

$$\begin{aligned} D_{X_1+X_2} Y(p) &= D_{X_1} Y(p) + D_{X_2} Y(p) \\ D_{fX} Y(p) &= f D_X Y(p) \\ D_X (Y_1 + Y_2)(p) &= D_X Y_1(p) + D_X Y_2(p) \\ D_X (fY)(p) &= X[f](p)Y(p) + f(p)D_X Y(p), \end{aligned}$$

for all $X, X_1, X_2, Y, Y_1, Y_2 \in \mathfrak{X}(U)$ and all $f \in C^\infty(U)$.

Now, if $p \in U$ where $U \subseteq M$ is an open subset of M , for any vector field, Y , defined on U ($Y(p) \in T_pM$, for all $p \in U$), for every $X \in T_pM$, the directional derivative, $D_X Y(p)$, makes sense and it has an orthogonal decomposition,

$$D_X Y(p) = \nabla_X Y(p) + (D_n)_X Y(p),$$

where its *horizontal (or tangential) component* is $\nabla_X Y(p) \in T_pM$ and its normal component is $(D_n)_X Y(p)$. See Figure 12.2.

Figure 12.2: The orthogonal decomposition of $D_X Y(p)$ for the peach surface M .

The component, $\nabla_X Y(p)$, is the *covariant derivative* of Y with respect to $X \in T_p M$ and it allows us to define the covariant derivative of a vector field, $Y \in \mathfrak{X}(U)$, with respect to a vector field, $X \in \mathfrak{X}(M)$, on M .

We easily check that $\nabla_X Y$ satisfies the four equations of Proposition 12.1.

In particular, Y , may be a vector field associated with a curve, $c: [0, 1] \rightarrow M$.

A *vector field along a curve, c* , is a vector field, Y , such that $Y(c(t)) \in T_{c(t)} M$, for all $t \in [0, 1]$. We also write $Y(t)$ for $Y(c(t))$.

Then, we say that *Y is parallel along c* iff $\nabla_{c'(t)} Y = 0$ along c .

The notion of *parallel transport* on a surface can be defined using parallel vector fields along curves. Let p, q be any two points on the surface M and assume there is a curve, $c: [0, 1] \rightarrow M$, joining $p = c(0)$ to $q = c(1)$.

Then, using the uniqueness and existence theorem for ordinary differential equations, it can be shown that for any initial tangent vector, $Y_0 \in T_pM$, there is a unique parallel vector field, Y , along c , with $Y(0) = Y_0$.

If we set $Y_1 = Y(1)$, we obtain a linear map, $Y_0 \mapsto Y_1$, from T_pM to T_qM which is also an isometry.

As a summary, given a surface, M , if we can define a notion of covariant derivative, $\nabla: \mathfrak{X}(M) \times \mathfrak{X}(M) \rightarrow \mathfrak{X}(M)$, satisfying the properties of Proposition 12.1, then we can define the notion of parallel vector field along a curve and the notion of parallel transport, which yields a natural way of relating two tangent spaces, T_pM and T_qM , using curves joining p and q .

This can be generalized to manifolds using the notion of connection. We will see that the notion of connection induces the notion of curvature. Moreover, if M has a Riemannian metric, we will see that this metric induces a unique connection with two extra properties (the *Levi-Civita* connection).

Definition 12.1. Let M be a smooth manifold.

A *connection* on M is a \mathbb{R} -bilinear map,

$$\nabla: \mathfrak{X}(M) \times \mathfrak{X}(M) \rightarrow \mathfrak{X}(M),$$

where we write $\nabla_X Y$ for $\nabla(X, Y)$, such that the following two conditions hold:

$$\begin{aligned} \nabla_{fX} Y &= f \nabla_X Y \\ \nabla_X (fY) &= X[f]Y + f \nabla_X Y, \end{aligned}$$

for all $X, Y \in \mathfrak{X}(M)$ and all $f \in C^\infty(M)$. The vector field, $\nabla_X Y$, is called the *covariant derivative of Y with respect to X* .

A connection on M is also known as an *affine connection* on M .

A basic property of ∇ is that it is a *local operator*.

Proposition 12.2. *Let M be a smooth manifold and let ∇ be a connection on M . For every open subset, $U \subseteq M$, for every vector field, $Y \in \mathfrak{X}(M)$, if $Y \equiv 0$ on U , then $\nabla_X Y \equiv 0$ on U for all $X \in \mathfrak{X}(M)$, that is, ∇ is a local operator.*

Proposition 12.2 implies that a connection, ∇ , on M , restricts to a connection, $\nabla \upharpoonright U$, on every open subset, $U \subseteq M$.

It can also be shown that $(\nabla_X Y)(p)$ only depends on $X(p)$, that is, for any two vector fields, $X, Y \in \mathfrak{X}(M)$, if $X(p) = Y(p)$ for some $p \in M$, then

$$(\nabla_X Z)(p) = (\nabla_Y Z)(p) \quad \text{for every } Z \in \mathfrak{X}(M).$$

Consequently, for any $p \in M$, the covariant derivative, $(\nabla_u Y)(p)$, is well defined for any tangent vector, $u \in T_p M$, and any vector field, Y , defined on some open subset, $U \subseteq M$, with $p \in U$.

Observe that on U , the n -tuple of vector fields, $\left(\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_n}\right)$, is a local frame.

We can write

$$\nabla_{\frac{\partial}{\partial x_i}} \left(\frac{\partial}{\partial x_j} \right) = \sum_{k=1}^n \Gamma_{ij}^k \frac{\partial}{\partial x_k},$$

for some unique smooth functions, Γ_{ij}^k , defined on U , called the *Christoffel symbols*.

We say that a connection, ∇ , is *flat* on U iff

$$\nabla_X \left(\frac{\partial}{\partial x_i} \right) = 0, \quad \text{for all } X \in \mathfrak{X}(U), 1 \leq i \leq n.$$

Proposition 12.3. *Every smooth manifold, M , possesses a connection.*

Proof. We can find a family of charts, $(U_\alpha, \varphi_\alpha)$, such that $\{U_\alpha\}_\alpha$ is a locally finite open cover of M . If (f_α) is a partition of unity subordinate to the cover $\{U_\alpha\}_\alpha$ and if ∇^α is the flat connection on U_α , then it is immediately verified that

$$\nabla = \sum_{\alpha} f_{\alpha} \nabla^{\alpha}$$

is a connection on M . □

Remark: A connection on TM can be viewed as a linear map,

$$\nabla: \mathfrak{X}(M) \longrightarrow \text{Hom}_{C^\infty(M)}(\mathfrak{X}(M), \mathfrak{X}(M)),$$

such that, for any fixed $Y \in \mathfrak{X}(M)$, the map,

$\nabla Y: X \mapsto \nabla_X Y$, is $C^\infty(M)$ -linear, which implies that ∇Y is a $(1, 1)$ tensor.

12.2 Parallel Transport

The notion of connection yields the notion of parallel transport. First, we need to define the covariant derivative of a vector field along a curve.

Definition 12.2. Let M be a smooth manifold and let $\gamma: [a, b] \rightarrow M$ be a smooth curve in M . A *smooth vector field along the curve γ* is a smooth map, $X: [a, b] \rightarrow TM$, such that $\pi(X(t)) = \gamma(t)$, for all $t \in [a, b]$ ($X(t) \in T_{\gamma(t)}M$). See Figure 12.3.

Figure 12.3: A smooth vector field along the orange curve γ .

Recall that the curve, $\gamma: [a, b] \rightarrow M$, is smooth iff γ is the restriction to $[a, b]$ of a smooth curve on some open interval containing $[a, b]$.

Since a vector X field along a curve γ does not necessarily extend to an open subset of M (for example, if the image of γ is dense in M), the covariant derivative $(\nabla_{\gamma'(t_0)} X)_{\gamma(t_0)}$ may not be defined, so we need a proposition showing that the covariant derivative of a vector field along a curve makes sense.

Proposition 12.4. *Let M be a smooth manifold, let ∇ be a connection on M and $\gamma: [a, b] \rightarrow M$ be a smooth curve in M . There is a unique \mathbb{R} -linear map, D/dt , defined on the vector space of smooth vector fields, X , along γ , which satisfies the following conditions:*

(1) *For any smooth function, $f: [a, b] \rightarrow \mathbb{R}$,*

$$\frac{D(fX)}{dt} = \frac{df}{dt} X + f \frac{DX}{dt}$$

(2) *If X is induced by a vector field, $Z \in \mathfrak{X}(M)$, that is, $X(t_0) = Z(\gamma(t_0))$ for all $t_0 \in [a, b]$, then*

$$\frac{DX}{dt}(t_0) = (\nabla_{\gamma'(t_0)} Z)_{\gamma(t_0)}.$$

Proof. Since $\gamma([a, b])$ is compact, it can be covered by a finite number of open subsets, U_α , such that $(U_\alpha, \varphi_\alpha)$ is a chart. Thus, we may assume that $\gamma: [a, b] \rightarrow U$ for some chart, (U, φ) . As $\varphi \circ \gamma: [a, b] \rightarrow \mathbb{R}^n$, we can write

$$\varphi \circ \gamma(t) = (u_1(t), \dots, u_n(t)),$$

where each $u_i = pr_i \circ \varphi \circ \gamma$ is smooth. Now, it is easy to see that

$$\gamma'(t_0) = \sum_{i=1}^n \frac{du_i}{dt} \left(\frac{\partial}{\partial x_i} \right)_{\gamma(t_0)}.$$

If (s_1, \dots, s_n) is a frame over U , we can write

$$X(t) = \sum_{i=1}^n X_i(t) s_i(\gamma(t)),$$

for some smooth functions, X_i .

If D/d exists, then, conditions (1) and (2) imply that

$$\frac{DX}{dt} = \sum_{j=1}^n \left(\frac{dX_j}{dt} s_j(\gamma(t)) + X_j(t) \nabla_{\gamma'(t)}(s_j(\gamma(t))) \right)$$

and since

$$\gamma'(t) = \sum_{i=1}^n \frac{du_i}{dt} \left(\frac{\partial}{\partial x_i} \right)_{\gamma(t)},$$

there exist some smooth functions, Γ_{ij}^k , so that

$$\begin{aligned} \nabla_{\gamma'(t)}(s_j(\gamma(t))) &= \sum_{i=1}^n \frac{du_i}{dt} \nabla_{\frac{\partial}{\partial x_i}}(s_j(\gamma(t))) \\ &= \sum_{i,k} \frac{du_i}{dt} \Gamma_{ij}^k s_k(\gamma(t)). \end{aligned}$$

It follows that

$$\frac{DX}{dt} = \sum_{k=1}^n \left(\frac{dX_k}{dt} + \sum_{ij} \Gamma_{ij}^k \frac{du_i}{dt} X_j \right) s_k(\gamma(t)),$$

which proves uniqueness.

Conversely, the above expression defines a linear operator, D/dt , and it is easy to check that it satisfies (1) and (2). \square

The operator, D/dt is often called *covariant derivative along γ* and it is also denoted by $\nabla_{\gamma'(t)}$ or simply $\nabla_{\gamma'}$.

Definition 12.3. Let M be a smooth manifold and let ∇ be a connection on M . For every curve, $\gamma: [a, b] \rightarrow M$, in M , a vector field, X , along γ is *parallel (along γ)* iff

$$\frac{DX}{dt}(s) = 0 \quad \text{for all } s \in [a, b].$$

If M was embedded in \mathbb{R}^d , for some d , then to say that X is parallel along γ would mean that the directional derivative, $(D_{\gamma'}X)(\gamma(t))$, is normal to $T_{\gamma(t)}M$. See Figure 12.4.

Figure 12.4: The real vector field X is parallel to the curve γ since $(D_{\gamma'} X)(\gamma(t))$ is perpendicular to the tangent plane $T_{\gamma(t)}M$.

The following proposition can be shown using the existence and uniqueness of solutions of ODE's (in our case, linear ODE's) and its proof is omitted:

Proposition 12.5. *Let M be a smooth manifold and let ∇ be a connection on M . For every C^1 curve, $\gamma: [a, b] \rightarrow M$, in M , for every $t \in [a, b]$ and every $v \in T_{\gamma(t)}M$, there is a unique parallel vector field, X , along γ such that $X(t) = v$.*

For the proof of Proposition 12.5 it is sufficient to consider the portions of the curve γ contained in some chart. In such a chart, (U, φ) , as in the proof of Proposition 12.4, using a local frame, (s_1, \dots, s_n) , over U , we have

$$\frac{DX}{dt} = \sum_{k=1}^n \left(\frac{dX_k}{dt} + \sum_{ij} \Gamma_{ij}^k \frac{du_i}{dt} X_j \right) s_k(\gamma(t)),$$

with $u_i = pr_i \circ \varphi \circ \gamma$. Consequently, X is parallel along our portion of γ iff the system of linear ODE's in the unknowns, X_k ,

$$\frac{dX_k}{dt} + \sum_{ij} \Gamma_{ij}^k \frac{du_i}{dt} X_j = 0, \quad k = 1, \dots, n,$$

is satisfied.

Remark: Proposition 12.5 can be extended to piecewise C^1 curves.

Definition 12.4. Let M be a smooth manifold and let ∇ be a connection on M . For every curve, $\gamma: [a, b] \rightarrow M$, in M , for every $t \in [a, b]$, the *parallel transport from $\gamma(a)$ to $\gamma(t)$ along γ* is the linear map from $T_{\gamma(a)}M$ to $T_{\gamma(t)}M$, which associates to any $v \in T_{\gamma(a)}M$ the vector, $X_v(t) \in T_{\gamma(t)}M$, where X_v is the unique parallel vector field along γ with $X_v(a) = v$. See Figure 12.5.

Figure 12.5: The parallel transport of the red vector field around the spherical triangle ABC .

The following proposition is an immediate consequence of properties of linear ODE's:

Proposition 12.6. *Let M be a smooth manifold and let ∇ be a connection on M . For every C^1 curve, $\gamma: [a, b] \rightarrow M$, in M , the parallel transport along γ defines for every $t \in [a, b]$ a linear isomorphism, $P_\gamma: T_{\gamma(a)}M \rightarrow T_{\gamma(t)}M$, between the tangent spaces, $T_{\gamma(a)}M$ and $T_{\gamma(t)}M$.*

In particular, if γ is a closed curve, that is, if $\gamma(a) = \gamma(b) = p$, we obtain a linear isomorphism, P_γ , of the tangent space, T_pM , called the *holonomy of γ* .

The *holonomy group of ∇ based at p* , denoted $\text{Hol}_p(\nabla)$, is the subgroup of $\text{GL}(n, \mathbb{R})$ (where n is the dimension of the manifold M) given by

$$\text{Hol}_p(\nabla) = \{P_\gamma \in \text{GL}(n, \mathbb{R}) \mid \gamma \text{ is a closed curve based at } p\}.$$

If M is connected, then $\text{Hol}_p(\nabla)$ depends on the basepoint $p \in M$ up to conjugation and so $\text{Hol}_p(\nabla)$ and $\text{Hol}_q(\nabla)$ are isomorphic for all $p, q \in M$. In this case, it makes sense to talk about the *holonomy group of ∇* . By abuse of language, we call $\text{Hol}_p(\nabla)$ the *holonomy group of M* .

12.3 Connections Compatible with a Metric; Levi-Civita Connections

If a Riemannian manifold, M , has a metric, then it is natural to define when a connection, ∇ , on M is compatible with the metric.

Given any two vector fields, $Y, Z \in \mathfrak{X}(M)$, the smooth function $\langle Y, Z \rangle$ is defined by

$$\langle Y, Z \rangle(p) = \langle Y_p, Z_p \rangle_p,$$

for all $p \in M$.

Definition 12.5. Given any metric, $\langle -, - \rangle$, on a smooth manifold, M , a connection, ∇ , on M is *compatible with the metric*, for short, a *metric connection* iff

$$X(\langle Y, Z \rangle) = \langle \nabla_X Y, Z \rangle + \langle Y, \nabla_X Z \rangle,$$

for all vector fields, $X, Y, Z \in \mathfrak{X}(M)$.

Proposition 12.7. *Let M be a Riemannian manifold with a metric, $\langle -, - \rangle$. Then, M , possesses metric connections.*

Proof. For every chart, $(U_\alpha, \varphi_\alpha)$, we use the Gram-Schmidt procedure to obtain an orthonormal frame over U_α and we let ∇^α be the flat connection over U_α . By construction, ∇^α is compatible with the metric. We finish the argument by using a partition of unity, leaving the details to the reader. \square

We know from Proposition 12.7 that metric connections on TM exist. However, there are many metric connections on TM and none of them seems more relevant than the others.

It is remarkable that if we require a certain kind of symmetry on a metric connection, then it is uniquely determined.

Such a connection is known as the *Levi-Civita connection*. The Levi-Civita connection can be characterized in several equivalent ways, a rather simple way involving the notion of torsion of a connection.

There are two *error terms* associated with a connection. The first one is the *curvature*,

$$R(X, Y) = \nabla_{[X, Y]} + \nabla_Y \nabla_X - \nabla_X \nabla_Y.$$

The second natural error term is the *torsion*, $T(X, Y)$, of the connection, ∇ , given by

$$T(X, Y) = \nabla_X Y - \nabla_Y X - [X, Y],$$

which measures the failure of the connection to behave like the Lie bracket.

Proposition 12.8. (*Levi-Civita, Version 1*) *Let M be any Riemannian manifold. There is a unique, metric, torsion-free connection, ∇ , on M , that is, a connection satisfying the conditions*

$$\begin{aligned} X(\langle Y, Z \rangle) &= \langle \nabla_X Y, Z \rangle + \langle Y, \nabla_X Z \rangle \\ \nabla_X Y - \nabla_Y X &= [X, Y], \end{aligned}$$

for all vector fields, $X, Y, Z \in \mathfrak{X}(M)$. This connection is called the *Levi-Civita connection* (or *canonical connection*) on M . Furthermore, this connection is determined by the *Koszul formula*

$$\begin{aligned} 2\langle \nabla_X Y, Z \rangle &= X(\langle Y, Z \rangle) + Y(\langle X, Z \rangle) - Z(\langle X, Y \rangle) \\ &\quad - \langle Y, [X, Z] \rangle - \langle X, [Y, Z] \rangle - \langle Z, [Y, X] \rangle. \end{aligned}$$

Proof. First, we prove uniqueness. Since our metric is a non-degenerate bilinear form, it suffices to prove the Koszul formula. As our connection is compatible with the metric, we have

$$\begin{aligned} X(\langle Y, Z \rangle) &= \langle \nabla_X Y, Z \rangle + \langle Y, \nabla_X Z \rangle \\ Y(\langle X, Z \rangle) &= \langle \nabla_Y X, Z \rangle + \langle X, \nabla_Y Z \rangle \\ -Z(\langle X, Y \rangle) &= -\langle \nabla_Z X, Y \rangle - \langle X, \nabla_Z Y \rangle \end{aligned}$$

and by adding up the above equations, we get

$$\begin{aligned} X(\langle Y, Z \rangle) + Y(\langle X, Z \rangle) - Z(\langle X, Y \rangle) &= \\ &= \langle Y, \nabla_X Z - \nabla_Z X \rangle \\ &+ \langle X, \nabla_Y Z - \nabla_Z Y \rangle \\ &+ \langle Z, \nabla_X Y + \nabla_Y X \rangle. \end{aligned}$$

Then, using the fact that the torsion is zero, we get

$$\begin{aligned} X(\langle Y, Z \rangle) + Y(\langle X, Z \rangle) - Z(\langle X, Y \rangle) &= \\ &= \langle Y, [X, Z] \rangle + \langle X, [Y, Z] \rangle \\ &+ \langle Z, [Y, X] \rangle + 2\langle Z, \nabla_X Y \rangle \end{aligned}$$

which yields the Koszul formula.

We will not prove existence here. The reader should consult the standard texts for a proof. \square

Remark: In a chart, (U, φ) , if we set

$$\partial_k g_{ij} = \frac{\partial}{\partial x_k}(g_{ij})$$

then it can be shown that the Christoffel symbols are given by

$$\Gamma_{ij}^k = \frac{1}{2} \sum_{l=1}^n g^{kl} (\partial_i g_{jl} + \partial_j g_{il} - \partial_l g_{ij}),$$

where (g^{kl}) is the inverse of the matrix (g_{kl}) .

It can be shown that a connection is torsion-free iff

$$\Gamma_{ij}^k = \Gamma_{ji}^k, \quad \text{for all } i, j, k.$$

We conclude this section with various useful facts about torsion-free or metric connections.

First, there is a nice characterization for the Levi-Civita connection induced by a Riemannian manifold over a submanifold.

Proposition 12.9. *Let M be any Riemannian manifold and let N be any submanifold of M equipped with the induced metric. If ∇^M and ∇^N are the Levi-Civita connections on M and N , respectively, induced by the metric on M , then for any two vector fields, X and Y in $\mathfrak{X}(M)$ with $X(p), Y(p) \in T_pN$, for all $p \in N$, we have*

$$\nabla_X^N Y = (\nabla_X^M Y)^\parallel,$$

where $(\nabla_X^M Y)^\parallel(p)$ is the orthogonal projection of $\nabla_X^M Y(p)$ onto T_pN , for every $p \in N$.

In particular, if γ is a curve on a surface, $M \subseteq \mathbb{R}^3$, then a vector field, $X(t)$, along γ is parallel iff $X'(t)$ is normal to the tangent plane, $T_{\gamma(t)}M$.

If ∇ is a metric connection, then we can say more about the parallel transport along a curve. Recall from Section 12.2, Definition 12.3, that a vector field, X , along a curve, γ , is parallel iff

$$\frac{DX}{dt} = 0.$$

Proposition 12.10. *Given any Riemannian manifold, M , and any metric connection, ∇ , on M , for every curve, $\gamma: [a, b] \rightarrow M$, on M , if X and Y are two vector fields along γ , then*

$$\frac{d}{dt} \langle X(t), Y(t) \rangle = \left\langle \frac{DX}{dt}, Y \right\rangle + \left\langle X, \frac{DY}{dt} \right\rangle.$$

Using Proposition 12.10 we get

Proposition 12.11. *Given any Riemannian manifold, M , and any metric connection, ∇ , on M , for every curve, $\gamma: [a, b] \rightarrow M$, on M , if X and Y are two vector fields along γ that are parallel, then*

$$\langle X, Y \rangle = C,$$

for some constant, C . In particular, $\|X(t)\|$ is constant. Furthermore, the linear isomorphism,

$P_\gamma: T_{\gamma(a)} \rightarrow T_{\gamma(b)}$, is an isometry.

In particular, Proposition 12.11 shows that the holonomy group, $\text{Hol}_p(\nabla)$, based at p , is a subgroup of $\mathbf{O}(n)$.
