the entries $\lambda_1, \ldots, \lambda_n$ in D (the eigenvalues of A) have absolute value $+1$. Thus, the entries in D are of the form $\cos\theta + i\sin\theta = e^{i\theta}$. Thus, we can assume that D is a diagonal matrix of the form

$$D = \begin{pmatrix} e^{i\theta_1} & & \ldots & \\ & e^{i\theta_2} & \ldots & \\ \vdots & \vdots & \ddots & \vdots \\ & & \ldots & e^{i\theta_p} \end{pmatrix}.$$

If we let E be the diagonal matrix

$$E = \begin{pmatrix} i\theta_1 & & \ldots & \\ & i\theta_2 & \ldots & \\ \vdots & \vdots & \ddots & \vdots \\ & & \ldots & i\theta_p \end{pmatrix}$$

it is obvious that E is skew Hermitian and that

$$e^E = D.$$

Then, letting $B = UEU^*$, we have

$$e^B = A,$$

and it is immediately verified that B is skew Hermitian, since E is.

If A is a unitary matrix with determinant $+1$, since the eigenvalues of A are $e^{i\theta_1}, \ldots, e^{i\theta_p}$ and the determinant of A is the product

$$e^{i\theta_1} \cdots e^{i\theta_p} = e^{i(\theta_1 + \cdots + \theta_p)}$$

of these eigenvalues, we must have

$$\theta_1 + \cdots + \theta_p = 0,$$

and so, E is skew Hermitian and has zero trace. As above, letting

$$B = UEU^*,$$

we have

$$e^B = A,$$

where B is skew Hermitian and has null trace. $\square$

We now extend the result of Section 14.3 to Hermitian matrices.

14.5 Hermitian Matrices, Hermitian Positive Definite Matrices, and the Exponential Map

Recall that a Hermitian matrix is called *positive* (or *positive semidefinite*) if its eigenvalues are all positive or null, and *positive definite* if its eigenvalues are all strictly positive. We denote the real vector space of Hermitian $n \times n$ matrices by $\mathbf{H}(n)$, the set of Hermitian positive matrices by $\mathbf{HP}(n)$, and the set of Hermitian positive definite matrices by $\mathbf{HPD}(n)$.

The next lemma shows that every Hermitian positive definite matrix A is of the form e^B for some unique Hermitian matrix B. As in the real case, the set of Hermitian matrices is a real vector space, but it is not a Lie algebra because the Lie bracket $[A, B]$ is not Hermitian unless A and B commute, and the set of Hermitian (positive) definite matrices is not a multiplicative group.

Lemma 14.5.1 *For every Hermitian matrix B, the matrix e^B is Hermitian positive definite. For every Hermitian positive definite matrix A, there is a unique Hermitian matrix B such that $A = e^B$.*

Proof. It is basically the same as the proof of Theorem 14.5.1, except that a Hermitian matrix can be written as $A = UDU^*$, where D is a real diagonal matrix and U is unitary instead of orthogonal. $\square$

Lemma 14.5.1 can be reformulated as stating that the map $\exp\colon \mathbf{H}(n) \to \mathbf{HPD}(n)$ is a bijection. In fact, it can be shown that it is a homeomorphism. In the case of complex invertible matrices, the polar form theorem can be reformulated as stating that there is a bijection between the topological space $\mathbf{GL}(n, \mathbb{C})$ of complex $n \times n$ invertible matrices (also a group) and $\mathbf{U}(n) \times \mathbf{HPD}(n)$. As a corollary of the polar form theorem and Lemma 14.5.1, we have the following result: For every complex invertible matrix A, there is a unique unitary matrix U and a unique Hermitian matrix S such that

$$A = U\, e^S.$$

Thus, we have a bijection between $\mathbf{GL}(n, \mathbb{C})$ and $\mathbf{U}(n) \times \mathbf{H}(n)$. But $\mathbf{H}(n)$ itself is isomorphic to $\mathbb{R}^{n^2}$, and so there is a bijection between $\mathbf{GL}(n, \mathbb{C})$ and $\mathbf{U}(n) \times \mathbb{R}^{n^2}$. It can also be shown that this bijection is a homeomorphism. This is an interesting fact. Indeed, this homeomorphism essentially reduces the study of the topology of $\mathbf{GL}(n, \mathbb{C})$ to the study of the topology of $\mathbf{U}(n)$. This is nice, since it can be shown that $\mathbf{U}(n)$ is compact (as a real manifold).

In the polar decomposition $A = Ue^S$, we have $|\det(U)| = 1$, since U is unitary, and $\mathrm{tr}(S)$ is real, since S is Hermitian (since it is the sum of the eigenvalues of S, which are real), so that $\det\left(e^S\right) > 0$. Thus, if $\det(A) = 1$, we must have $\det\left(e^S\right) = 1$, which implies that $S \in \mathbf{H}(n) \cap \mathfrak{sl}(n, \mathbb{C})$. Thus, we have a bijection between $\mathbf{SL}(n, \mathbb{C})$ and $\mathbf{SU}(n) \times (\mathbf{H}(n) \cap \mathfrak{sl}(n, \mathbb{C}))$.

In the next section we study the group $\mathbf{SE}(n)$ of affine maps induced by orthogonal transformations, also called rigid motions, and its Lie algebra. We will show that the exponential map is surjective. The groups $\mathbf{SE}(2)$ and $\mathbf{SE}(3)$ play play a fundamental role in robotics, dynamics, and motion planning.
