And give a formalization of Adam Smith's "Invisible Hand"

Overview

- So far we have studied several mechanism design problems without money.
- An "exchange" and a "matching" problem.
- This lecture: We'll bring money into the picture in a matching like problem.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- And give a formalization of Adam Smith's "Invisible Hand"
- The thesis (in our simple model): simple, decentralized market dynamics lead to efficient outcomes.

Suppose we have:

◆□▶ ◆□▶ ◆ 臣▶ ◆ 臣▶ ○ 臣 ○ の Q @

Suppose we have:

1. *m goods G* for sale

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Suppose we have:

- 1. $m \ goods \ G$ for sale
- 2. *n* buyers *i* who each have valuation functions over bundles, $v_i: 2^G \rightarrow [0, 1].$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Suppose we have:

- 1. *m goods G* for sale
- 2. *n* buyers *i* who each have valuation functions over bundles, $v_i: 2^G \rightarrow [0, 1].$

Buyers have quasi-linear utility functions: If each good $j \in G$ has a price p_i , then a buyer i gets utility for buying a bundle $S \subseteq G$:

$$u_i(S) = v_i(S) - \sum_{j \in S} p_j$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

Suppose we have:

- 1. *m goods G* for sale
- 2. *n* buyers *i* who each have valuation functions over bundles, $v_i: 2^G \rightarrow [0, 1].$

Buyers have quasi-linear utility functions: If each good $j \in G$ has a price p_i , then a buyer i gets utility for buying a bundle $S \subseteq G$:

$$u_i(S) = v_i(S) - \sum_{j \in S} p_j$$

Questions: How we should *price* and *allocate* goods so that everyone is happy with their allocation. Is this even possible? If it is, can we do so and *also* achieve a high welfare allocation?

Some Definitions

First, feasibility:

Definition

An allocation $S_1, \ldots, S_n \subseteq G$ is *feasible* if for all $i \neq j$, $S_i \cap S_j = \emptyset$ We write OPT to denote the socially optimal feasible allocation:

$$OPT = \max_{S_1,...,S_n \text{ feasible}} \sum_i v_i(S)$$

Some Definitions

Definition

A set of prices p together with an allocation S_1, \ldots, S_n form an (ϵ -approximate) Walrasian equilibrium if:

- 1. S_1, \ldots, S_n is feasible, and
- 2. For all *i*, buyer *i* is receiving his (ϵ) most preferred bundle given the prices:

$$v_i(S_i) - \sum_{j \in S_i} p_j \geq \max_{S^* \subseteq G} \left(v_i(S^*) - \sum_{j \in S^*} p_j
ight) - \epsilon$$

and,

3. All unallocated items have zero price: for all $j \notin S_1 \cup \ldots \cup S_n$, $p_j = 0$.

Some Questions:

Some Questions:

1. Do Walrasian equilibria always exist?

Some Questions:

- 1. Do Walrasian equilibria always exist?
- 2. If so, are they compatible with social welfare maximization?

The 2nd Question 1st

Theorem

If S_1, \ldots, S_n form an ϵ -Walrasian equilibrium allocation, then they achieve nearly optimal welfare. In particular:

$$\sum_{i} v_i(S_i) \ge \text{OPT} - \epsilon n$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

1. Let p be the corresponding Walrasian equilibrium prices, and let S'_1, \ldots, S'_n be any other feasible allocation.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

- 1. Let p be the corresponding Walrasian equilibrium prices, and let S'_1, \ldots, S'_n be any other feasible allocation.
- 2. We know from the 2nd Walrasian equilibrium condition that for every player *i*, we have:

$$v_i(S_i) - \sum_{j \in S_i} p_j \ge v_i(S'_i) - \sum_{j \in S'_i} p_j - \epsilon$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

- 1. Let p be the corresponding Walrasian equilibrium prices, and let S'_1, \ldots, S'_n be any other feasible allocation.
- 2. We know from the 2nd Walrasian equilibrium condition that for every player *i*, we have:

$$v_i(S_i) - \sum_{j \in S_i} p_j \ge v_i(S'_i) - \sum_{j \in S'_i} p_j - \epsilon$$

3. Summing over buyers:

$$\sum_{i} \left(v_i(S_i) - \sum_{j \in S_i} p_j \right) \ge \sum_{i} \left(v_i(S'_i) - \sum_{j \in S'_i} p_j \right) - \epsilon n$$

- 1. Let p be the corresponding Walrasian equilibrium prices, and let S'_1, \ldots, S'_n be any other feasible allocation.
- 2. We know from the 2nd Walrasian equilibrium condition that for every player *i*, we have:

$$v_i(S_i) - \sum_{j \in S_i} p_j \ge v_i(S'_i) - \sum_{j \in S'_i} p_j - \epsilon$$

3. Summing over buyers:

$$\sum_{i} \left(v_i(S_i) - \sum_{j \in S_i} p_j \right) \ge \sum_{i} \left(v_i(S'_i) - \sum_{j \in S'_i} p_j \right) - \epsilon n$$

4. Reordering:

$$\sum_{i} v_i(S_i) - \sum_{j \in S_1 \cup \ldots \cup S_n} p_j \ge \sum_{i} v_i(S'_i) - \sum_{j \in S'_1 \cup \ldots \cup S'_n} p_j - \epsilon n$$

うせん 同一人用 (一日) (日)

$$\sum_{i} v_i(S_i) - \sum_{j \in S_1 \cup \ldots \cup S_n} p_j \ge \sum_{i} v_i(S'_i) - \sum_{j \in S'_1 \cup \ldots \cup S'_n} p_j - \epsilon n$$

$$\sum_{i} v_i(S_i) - \sum_{j \in S_1 \cup \ldots \cup S_n} p_j \ge \sum_{i} v_i(S'_i) - \sum_{j \in S'_1 \cup \ldots \cup S'_n} p_j - \epsilon n$$

1. for any $j \notin S_1 \cup \ldots \cup S_n$, we must have $p_j = 0$. So, on the LHS we have: $\sum_{j \in S_1 \cup \ldots \cup S_n} p_j = \sum_j p_j$

$$\sum_{i} v_i(S_i) - \sum_{j \in S_1 \cup \ldots \cup S_n} p_j \ge \sum_{i} v_i(S'_i) - \sum_{j \in S'_1 \cup \ldots \cup S'_n} p_j - \epsilon n$$

- 1. for any $j \notin S_1 \cup \ldots \cup S_n$, we must have $p_j = 0$. So, on the LHS we have: $\sum_{j \in S_1 \cup \ldots \cup S_n} p_j = \sum_j p_j$
- 2. Rewriting:

$$\sum_{i} v_i(S_i) \geq \sum_{i} v_i(S'_i) + (\sum_{j} p_j - \sum_{j \in S'_1 \cup \dots \cup S'_n} p_j) - \epsilon n \geq \sum_{i} v_i(S'_i) - \epsilon n$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

$$\sum_{i} v_i(S_i) - \sum_{j \in S_1 \cup \ldots \cup S_n} p_j \ge \sum_{i} v_i(S'_i) - \sum_{j \in S'_1 \cup \ldots \cup S'_n} p_j - \epsilon n$$

- 1. for any $j \notin S_1 \cup \ldots \cup S_n$, we must have $p_j = 0$. So, on the LHS we have: $\sum_{j \in S_1 \cup \ldots \cup S_n} p_j = \sum_j p_j$
- 2. Rewriting:

$$\sum_{i} v_i(S_i) \ge \sum_{i} v_i(S'_i) + (\sum_{j} p_j - \sum_{j \in S'_1 \cup \dots \cup S'_n} p_j) - \epsilon n \ge \sum_{i} v_i(S'_i) - \epsilon n$$

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬる

3. Finally, taking S'_1, \ldots, S'_n to be the optimal allocation gives the theorem. (Tada!)

Walrasian Equilibrium are Great! Do They Exist?

1. We'll start with a simple case: unit demand buyers (want to buy only 1 item):

$$v_i(S) = \max_{j \in S} v_i(\{j\})$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

We can think about such a valuation function as being determined by just *m* numbers, one for each good: $v_{i,j} \equiv v_i(\{j\}) \leq 1$

Walrasian Equilibrium are Great! Do They Exist?

1. We'll start with a simple case: unit demand buyers (want to buy only 1 item):

- 1. We will see on the homework that Walrasian equilibrium need not exist for *all* valuation functions.
- 2. But how far can we push beyond unit demand?
- 3. What was needed to make the analysis of the dynamics work for more general valuations?
- 4. We can define the dynamics: each *unsatisfied* bidder bids on their most preferred *bundle* (Unsatisified = not matched to her ϵ -most preferred bundle). For each unsatisfied bidder *i*:
 - 4.1 *i* bids on every item she is not the high bidder on in a set $S^* \in \arg \max_{S \subseteq G} (v_i(S) - \sum_{j \in S} p_j)$ 4.2 For all $j \in S^*$, $\mu(j) \leftarrow i$, $p_i \leftarrow p_i + \epsilon/m$.

1. After a bidder bids, she is matched to her ϵ -most preferred bundle, and she remains so if she is not out-bid on any of her items (since other prices only rise).

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- 1. After a bidder bids, she is matched to her ϵ -most preferred bundle, and she remains so if she is not out-bid on any of her items (since other prices only rise).
- 2. We also needed that once a good became matched, it stayed matched (so that unmatched goods have price 0).

- 1. After a bidder bids, she is matched to her ϵ -most preferred bundle, and she remains so if she is not out-bid on any of her items (since other prices only rise).
- 2. We also needed that once a good became matched, it stayed matched (so that unmatched goods have price 0).
- 3. So we do not want that when a bidder *i* bids, she abandons any of the goods she is currently matched to.

- 2. We also needed that once a good became matched, it stayed matched (so that unmatched goods have price 0).
- 3. So we do not want that when a bidder *i* bids, she abandons any of the goods she is currently matched to.

4. We can formalize this.

1. For price vectors p, p', write $p \leq p'$ to mean that $p_j \leq p'_j$ for all j. Let $w_i(p) = \arg \max_{S \subseteq G} (v_i(S) - \sum_{j \in S} p_j)$ be player *i*'s demand set at prices p.

Definition

Valuation function v_i satisfies the gross substitutes property if for every $p \leq p'$ and for every $S \in w_i(p)$, if $S' = \{j \in S : p_j = p'_j\}$, then there exits $S^* \in w_i(p')$ such that $S' \subseteq S^*$. In other words, "Raising the prices on goods $j \neq i$ doesn't decrease a bidder's demand for good j".

Definition

Valuation function v_i satisfies the gross substitutes property if for every $p \leq p'$ and for every $S \in w_i(p)$, if $S' = \{j \in S : p_j = p'_j\}$, then there exits $S^* \in w_i(p')$ such that $S' \subseteq S^*$. In other words, "Raising the prices on goods $j \neq i$ doesn't decrease a bidder's demand for good j".

2. This is what we need: Any good for which bidder *i* has not been out-bid on has not had its price raised, and so must still be part of a bundle in bidder *i*'s demand set.

- 2. This is what we need: Any good for which bidder *i* has not been out-bid on has not had its price raised, and so must still be part of a bundle in bidder *i*'s demand set.
- 3. Hence, we have:

Theorem

In any market in which all buyers satisfy the gross substitutes condition, Walrasian equilibria exist.

Thanks!

See you next class — stay healthy!
