# Dynamic Pricing: Profit Maximization From "Bandit" Feedback

#### Aaron Roth

University of Pennsylvania

April 16 2024

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Last lecture, we gave an online auction for maximizing revenue in digital goods settings.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

- Last lecture, we gave an online auction for maximizing revenue in digital goods settings.
- But it was an "auction" rather than a "pricing scheme" because bidders had to report their valuations.

- Last lecture, we gave an online auction for maximizing revenue in digital goods settings.
- But it was an "auction" rather than a "pricing scheme" because bidders had to report their valuations.
- More practical/realistic if we just post prices and let buyers make purchase decisions.

- Last lecture, we gave an online auction for maximizing revenue in digital goods settings.
- But it was an "auction" rather than a "pricing scheme" because bidders had to report their valuations.
- More practical/realistic if we just post prices and let buyers make purchase decisions.
- But also more complex, because we don't get the feedback needed to run the polynomial weights algorithm.

- Last lecture, we gave an online auction for maximizing revenue in digital goods settings.
- But it was an "auction" rather than a "pricing scheme" because bidders had to report their valuations.
- More practical/realistic if we just post prices and let buyers make purchase decisions.
- But also more complex, because we don't get the feedback needed to run the polynomial weights algorithm.
- This lecture: solve this kind of "censored" learning problem when bidders are drawn from a distribution.

- Last lecture, we gave an online auction for maximizing revenue in digital goods settings.
- But it was an "auction" rather than a "pricing scheme" because bidders had to report their valuations.
- More practical/realistic if we just post prices and let buyers make purchase decisions.
- But also more complex, because we don't get the feedback needed to run the polynomial weights algorithm.
- This lecture: solve this kind of "censored" learning problem when bidders are drawn from a distribution.
- Its also possible to solve the problem without the distributional assumption... Just more complicated.

We can offer fixed prices, and just observe whether buyers take or leave them. (Not their values).

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

- We can offer fixed prices, and just observe whether buyers take or leave them. (Not their values).
- We know nothing about the instance at the start, but learn as we go (and can change prices as we learn).

- We can offer fixed prices, and just observe whether buyers take or leave them. (Not their values).
- We know nothing about the instance at the start, but learn as we go (and can change prices as we learn).

### Definition

In a dynamic pricing setting, there are *n* buyers, each with valuation  $v_i \in [0, 1]$  drawn independently from some unknown distribution  $\mathcal{D}$ .

- 1. At time *t*, the seller sets some price  $p_t \in [0, 1]$ .
- 2. Buyer t arrives with  $v_t \sim D$ . If  $v_t \geq p_t$ , the buyer purchases the good, and the seller gets revenue  $p_t$ . Otherwise, the buyer declines to purchase the good, and the seller gets revenue 0.

# A Learning Approach

We continue to want to compete with the bext fixed price benchmark:

$$OPT = \max_{p} p \cdot \Pr[v \ge p] \cdot n$$

◆□▶ ◆□▶ ◆ 臣▶ ◆ 臣▶ ○ 臣 ○ の Q @

## A Learning Approach

We continue to want to compete with the bext fixed price benchmark:

$$OPT = \max_{p} p \cdot \Pr[v \ge p] \cdot n$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Our approach last lecture was to reduce the problem to an online learning problem, and solve it using the PW algorithm.

## A Learning Approach

We continue to want to compete with the bext fixed price benchmark:

$$OPT = \max_{p} p \cdot \Pr[v \ge p] \cdot n$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- Our approach last lecture was to reduce the problem to an online learning problem, and solve it using the PW algorithm.
- We'll try and do the same thing this lecture. We need to define a learning problem with more restricted feedback.

## **Bandit Problems**

#### Definition

In the multi-armed bandit problem, there are k "arms" *i*, each of which is associated with a payoff distribution  $\mathcal{D}_i$  over [0, 1] with mean  $\mu_i$ . In rounds *t*, the algorithm chooses arm  $i_t$  and receives reward  $r_{i_t}^t \sim \mathcal{D}_i$ .

### Bandit Problems

#### Definition

In the multi-armed bandit problem, there are k "arms" i, each of which is associated with a payoff distribution  $\mathcal{D}_i$  over [0, 1] with mean  $\mu_i$ . In rounds t, the algorithm chooses arm  $i_t$  and receives reward  $r_{i_t}^t \sim \mathcal{D}_i$ .

The expected reward of the algorithm after T days is  $\sum_{t=1}^{T} \mu_{i_t}$ . The *regret* of the algorithm is:

$$\textit{Regret}(\textit{T}) = \textit{T} \cdot \mu_{i^*} - \sum_{t=1}^{T} \mu_{i_t}$$

where  $i^* = \arg \max_i \mu_i$  is the arm with highest expected reward.

Idea: "optimism in the face of uncertainty".

- Idea: "optimism in the face of uncertainty".
- We will quantify uncertainty about the mean payoff of each arm *i* by maintaining a confidence interval around its empirical estimate.

- Idea: "optimism in the face of uncertainty".
- We will quantify uncertainty about the mean payoff of each arm *i* by maintaining a confidence interval around its empirical estimate.
- We will then behave greedily but not by playing the arm with the highest empirical mean so far, but rather by playing the arm with the highest upper confidence bound.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- Idea: "optimism in the face of uncertainty".
- We will quantify uncertainty about the mean payoff of each arm *i* by maintaining a confidence interval around its empirical estimate.
- We will then behave greedily but not by playing the arm with the highest empirical mean so far, but rather by playing the arm with the highest upper confidence bound.
- This is being optimistic imagining that each arm is as good as it could possibly be, consistent with the evidence.

### Theorem (Chernoff-Hoeffding Bound)

Let  $\mathcal{D}$  be any distribution over [0,1] with mean  $\mu$ , and let  $X_1, \ldots, X_n \sim \mathcal{D}$  be independent draws. Then for any  $0 \leq \delta \leq 1$ :

$$\Pr\left[\left|\frac{1}{n}\sum_{i=1}^{n}X_{i}-\mu\right| \leq \sqrt{\frac{\ln\left(\frac{2}{\delta}\right)}{2n}}\right] \geq 1-\delta$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

### The Algorithm

**UCB(**δ, T):

Define  $w(n) = \sqrt{\frac{\ln(\frac{2T}{\delta})}{2n}}$ . Initialize empirical means  $\hat{\mu}_i^0 \leftarrow 1/2$ and upper and lower confidence bounds  $u_i^0 \leftarrow 1, \ell_i^0 \leftarrow 0$  for each arm *i*. Initialize play counts  $n_i^t \leftarrow 0$  for each arm *i*. **for** t = 1 to T **do** 

Pick an arm  $i_t \in \arg \max u_i^{t-1}$ . Observe reward  $r_{i_t}^t$ . Update: For each  $i \neq i_t$ , set  $(\hat{\mu}_i^t, u_i^t, \ell_i^t, n_i^t) \leftarrow (\hat{\mu}_i^{t-1}, u_i^{t-1}, \ell_i^{t-1}, n_i^{t-1})$ For  $i = i_t$ ,  $n_i^t \leftarrow n_i^{t-1} + 1$ ,  $\hat{\mu}_i^t \leftarrow \frac{n_i^{t-1}}{n_i^t} \hat{\mu}_i^{t-1} + \frac{1}{n_i^t} r_i^t$ ,  $u_i^t \leftarrow \hat{\mu}_i^t + w(n_i^t)$ ,  $\ell_i^t \leftarrow \hat{\mu}_i^t - w(n_i^t)$ end for

### Regret

#### Theorem

For any set of k arms, with probability  $1 - \delta$ , the UCB algorithm obtains regret:

$$Regret(T) \leq O\left(\sqrt{k \cdot T \cdot \ln\left(\frac{T}{\delta}\right)}\right)$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

► Observe that the widths of the confidence intervals w maintained by the UCB algorithm are defined such that (by the Chernoff-Hoeffding bound): for each t and i, with probability 1 - δ/T:

 $\mu_i \in [u_i^t, \ell_i^t].$ 

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

► Observe that the widths of the confidence intervals w maintained by the UCB algorithm are defined such that (by the Chernoff-Hoeffding bound): for each t and i, with probability 1 - δ/T:

### $\mu_i \in [u_i^t, \ell_i^t].$

Since there are *T* confidence intervals constructed over the run of the algorithm, with probability 1 − δ, simultaneously for all *i* and *t*:

$$\mu_i \in [u_i^t, \ell_i^t].$$

► Observe that the widths of the confidence intervals w maintained by the UCB algorithm are defined such that (by the Chernoff-Hoeffding bound): for each t and i, with probability 1 - δ/T:

### $\mu_i \in [u_i^t, \ell_i^t].$

Since there are *T* confidence intervals constructed over the run of the algorithm, with probability 1 − δ, simultaneously for all *i* and *t*:

$$\mu_i \in [u_i^t, \ell_i^t].$$

For the rest of the argument, we will assume that this is the case.

Suppose at day t we play action i<sub>t</sub>, obtaining expected payoff μ<sub>it</sub>.

(ロ)、(型)、(E)、(E)、(E)、(O)へ(C)

- Suppose at day t we play action i<sub>t</sub>, obtaining expected payoff µ<sub>it</sub>.
- How much worse is this than μ<sub>i\*</sub>, the expected payoff of the optimal arm? Since by definition i<sub>t</sub> = arg max<sub>i</sub> u<sub>i</sub><sup>t-1</sup>, and because all of the confidence intervals are valid, we have:

$$\mu_{i_t} \geq \ell_{i_t}^{t-1} = u_{i_t}^{t-1} - 2w(n_{i_t}^{t-1}) \geq u_{i^*}^{t-1} - 2w(n_{i_t}^{t-1}) \geq \mu_{i^*} - 2w(n_{i_t}^{t-1})$$

- Suppose at day t we play action i<sub>t</sub>, obtaining expected payoff μ<sub>it</sub>.
- How much worse is this than μ<sub>i\*</sub>, the expected payoff of the optimal arm? Since by definition i<sub>t</sub> = arg max<sub>i</sub> u<sub>i</sub><sup>t-1</sup>, and because all of the confidence intervals are valid, we have:

$$\mu_{i_t} \geq \ell_{i_t}^{t-1} = u_{i_t}^{t-1} - 2w(n_{i_t}^{t-1}) \geq u_{i^*}^{t-1} - 2w(n_{i_t}^{t-1}) \geq \mu_{i^*} - 2w(n_{i_t}^{t-1})$$

So the regret incurred at round t is:

$$\mu_{i^*} - \mu_{i_t} \leq 2w(n_{i_t}^{t-1})$$

- Suppose at day t we play action i<sub>t</sub>, obtaining expected payoff μ<sub>it</sub>.
- How much worse is this than μ<sub>i\*</sub>, the expected payoff of the optimal arm? Since by definition i<sub>t</sub> = arg max<sub>i</sub> u<sub>i</sub><sup>t-1</sup>, and because all of the confidence intervals are valid, we have:

$$\mu_{i_t} \geq \ell_{i_t}^{t-1} = u_{i_t}^{t-1} - 2w(n_{i_t}^{t-1}) \geq u_{i^*}^{t-1} - 2w(n_{i_t}^{t-1}) \geq \mu_{i^*} - 2w(n_{i_t}^{t-1})$$

So the regret incurred at round t is:

$$\mu_{i^*} - \mu_{i_t} \leq 2w(n_{i_t}^{t-1})$$

Or see picture...

So we can bound overall regret as:

$$Regret(T) \leq 2\sum_{t=1}^{T} w(n_{i_t}^{t-1})$$

So we can bound overall regret as:

$$Regret(T) \leq 2\sum_{t=1}^{T} w(n_{i_t}^{t-1})$$
$$= 2\sum_{i=1}^{k} \sum_{n=1}^{n_i^T} w(n)$$

◆□▶ ◆□▶ ◆ 臣▶ ◆ 臣▶ ○ 臣 ○ の Q @

So we can bound overall regret as:

$$Regret(T) \leq 2\sum_{t=1}^{T} w(n_{i_t}^{t-1})$$
$$= 2\sum_{i=1}^{k} \sum_{n=1}^{n_i^T} w(n)$$
$$\leq 2\sum_{i=1}^{k} \sum_{n=1}^{T/k} w(n)$$

So we can bound overall regret as:

$$Regret(T) \leq 2\sum_{t=1}^{T} w(n_{i_t}^{t-1})$$
$$= 2\sum_{i=1}^{k} \sum_{n=1}^{n_i^T} w(n)$$
$$\leq 2\sum_{i=1}^{k} \sum_{n=1}^{T/k} w(n)$$
$$= 2\sum_{i=1}^{k} \sum_{n=1}^{T/k} \sqrt{\frac{\ln\left(\frac{2T}{\delta}\right)}{2n}}$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

So we can bound overall regret as:

$$Regret(T) \leq 2 \sum_{t=1}^{T} w(n_{i_t}^{t-1})$$

$$= 2 \sum_{i=1}^{k} \sum_{n=1}^{n_i^T} w(n)$$

$$\leq 2 \sum_{i=1}^{k} \sum_{n=1}^{T/k} w(n)$$

$$= 2 \sum_{i=1}^{k} \sum_{n=1}^{T/k} \sqrt{\frac{\ln(\frac{2T}{\delta})}{2n}}$$

$$= 2 \sum_{i=1}^{k} \sqrt{\frac{\ln(\frac{2T}{\delta})}{2}} \sum_{n=1}^{T/k} \frac{1}{\sqrt{n}}$$

◆□ ▶ ◆□ ▶ ◆ 臣 ▶ ◆ 臣 ▶ ○ 臣 ○ の Q @

So we can bound overall regret as:

$$Regret(T) \leq 2\sum_{t=1}^{T} w(n_{i_t}^{t-1})$$

$$= 2\sum_{i=1}^{k} \sum_{n=1}^{n_i^T} w(n)$$

$$\leq 2\sum_{i=1}^{k} \sum_{n=1}^{T/k} w(n)$$

$$= 2\sum_{i=1}^{k} \sum_{n=1}^{T/k} \sqrt{\frac{\ln\left(\frac{2T}{\delta}\right)}{2n}}$$

$$= 2\sum_{i=1}^{k} \sqrt{\frac{\ln\left(\frac{2T}{\delta}\right)}{2}} \sum_{n=1}^{T/k} \frac{1}{\sqrt{n}}$$

$$\leq O\left(\sqrt{k \cdot T \cdot \ln\left(\frac{T}{\delta}\right)}\right)$$

We will pick a set k "arms", associating each one with a price from K = {α, 2α, 3α, ..., 1}.

- We will pick a set k "arms", associating each one with a price from K = {α, 2α, 3α,..., 1}.
- Note that k = |K| = 1/α. The distribution on rewards for each arm p is simply the distribution on revenue when deploying a price p − realizing reward r<sub>p</sub> = p with probability Pr[v ≥ p] and reward r<sub>p</sub> = 0 otherwise.

- We will pick a set k "arms", associating each one with a price from K = {α, 2α, 3α,..., 1}.
- Note that k = |K| = 1/α. The distribution on rewards for each arm p is simply the distribution on revenue when deploying a price p − realizing reward r<sub>p</sub> = p with probability Pr[v ≥ p] and reward r<sub>p</sub> = 0 otherwise.
- For every price  $p \in [0, 1]$ , there is another price  $p' \in K$  such that  $p \alpha \leq p' \leq p$ .

- We will pick a set k "arms", associating each one with a price from K = {α, 2α, 3α,...,1}.
- Note that k = |K| = 1/α. The distribution on rewards for each arm p is simply the distribution on revenue when deploying a price p − realizing reward r<sub>p</sub> = p with probability Pr[v ≥ p] and reward r<sub>p</sub> = 0 otherwise.
- For every price p ∈ [0, 1], there is another price p' ∈ K such that p − α ≤ p' ≤ p.
- So in a setting with n buyers, we have:

$$\max_{p \in K} p \cdot \Pr[v \ge p] \cdot n \ge \max_{p \in [0,1]} p \cdot \Pr[v \ge p] \cdot n - \alpha n$$

• Using the guarantees of the UCB algorithm we have that except with probability  $\delta$ :

$$Revenue(UCB) \ge \max_{p \in K} p \cdot \Pr[v \ge p] \cdot n - O\left(\sqrt{k \cdot n \cdot \ln\left(\frac{n}{\delta}\right)}\right)$$
$$\ge OPT - \alpha n - O\left(\sqrt{\frac{n}{\alpha} \cdot \ln\left(\frac{n}{\delta}\right)}\right)$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Using the guarantees of the UCB algorithm we have that except with probability δ:

$$Revenue(UCB) \ge \max_{p \in K} p \cdot \Pr[v \ge p] \cdot n - O\left(\sqrt{k \cdot n \cdot \ln\left(\frac{n}{\delta}\right)}\right)$$
$$\ge OPT - \alpha n - O\left(\sqrt{\frac{n}{\alpha} \cdot \ln\left(\frac{n}{\delta}\right)}\right)$$

Choosing

$$\alpha = \left(\frac{\log(n/\delta)}{n}\right)^{1/3}$$

yields:

$$\mathsf{Revenue}(\mathsf{UCB}) \geq \mathrm{OPT} - O\left(n^{2/3}\log(n/\delta)^{1/3}
ight)$$

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへで

Using the guarantees of the UCB algorithm we have that except with probability δ:

$$Revenue(UCB) \ge \max_{p \in K} p \cdot \Pr[v \ge p] \cdot n - O\left(\sqrt{k \cdot n \cdot \ln\left(\frac{n}{\delta}\right)}\right)$$
$$\ge OPT - \alpha n - O\left(\sqrt{\frac{n}{\alpha} \cdot \ln\left(\frac{n}{\delta}\right)}\right)$$

Choosing

$$\alpha = \left(\frac{\log(n/\delta)}{n}\right)^{1/3}$$

yields:

$$Revenue(UCB) \ge OPT - O\left(n^{2/3}\log(n/\delta)^{1/3}\right)$$

► So if 
$$OPT(n) = \omega (n^{2/3} \log(n/\delta)^{1/3})$$
, then   
*Revenue(UCB)* ≥  $(1 - o(1))OPT$ .

 Using the guarantees of the UCB algorithm we have that except with probability δ:

$$Revenue(UCB) \ge \max_{p \in K} p \cdot \Pr[v \ge p] \cdot n - O\left(\sqrt{k \cdot n \cdot \ln\left(\frac{n}{\delta}\right)}\right)$$
$$\ge OPT - \alpha n - O\left(\sqrt{\frac{n}{\alpha} \cdot \ln\left(\frac{n}{\delta}\right)}\right)$$

Choosing

$$\alpha = \left(\frac{\log(n/\delta)}{n}\right)^{1/3}$$

yields:

$$Revenue(UCB) \ge OPT - O\left(n^{2/3}\log(n/\delta)^{1/3}\right)$$

- ► So if  $OPT(n) = \omega (n^{2/3} \log(n/\delta)^{1/3})$ , then *Revenue*(*UCB*) ≥ (1 - o(1))OPT.
- For any non-trivial distribution, this is the case (since OPT(n) grows linearly with n).

### Thanks!
