

2.1 Functions

Functions

- Take in input arguments (zero or more)
- Perform some computation
 - May have side-effects (such as drawing)
- Return one output value

Functions (Static Methods)

- Applications:
 - Use mathematical functions to calculate formulas
 - Use functions to build modular programs

- Examples:
 - Built-in functions:

`Math.random()`, `Math.abs()`, `Integer.parseInt()`

These methods return, respectively, a double, double, and int value.

- I/O libraries:

`PennDraw.circle(x,y,halfRadius)` ,

`PennDraw.line(x0,y0,x1,y1)`

- User-defined functions:

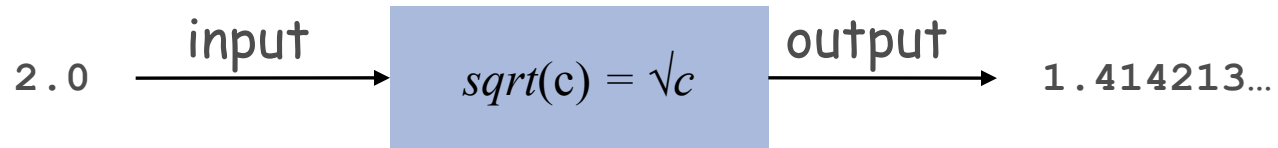

`main()`

Why do we need functions?

- Break code down into logical sub-steps
- Readability of the code improves
- Testability - focus on getting each individual function correct

Anatomy of a Java Function

- Java functions – It is easy to write your own
 - Example: `double sqrt(double c)`

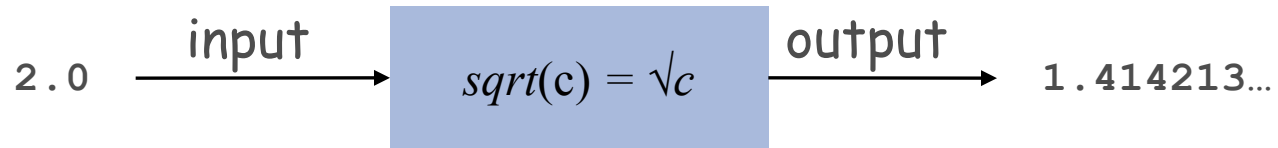

```
public static return type double method name sqrt(arguments double c) {  
    ...  
}
```

method signature
(excludes return type)

Please note that the method signature is defined incorrectly in the figure on pg 188 of your textbook

Anatomy of a Java Function

- Java functions – It is easy to write your own
 - Example: `double sqrt(double c)`

```
public static double sqrt(double c)
```

```
{
```

*local
variables*

```
    if (c < 0) return Double.NaN;
```

```
    double err = 1e-15;
```

```
    double t = c;
```

*method
body*

```
    while (Math.abs(t - c/t) > err * t)  
        t = (c/t + t) / 2.0;
```

```
    return t;
```

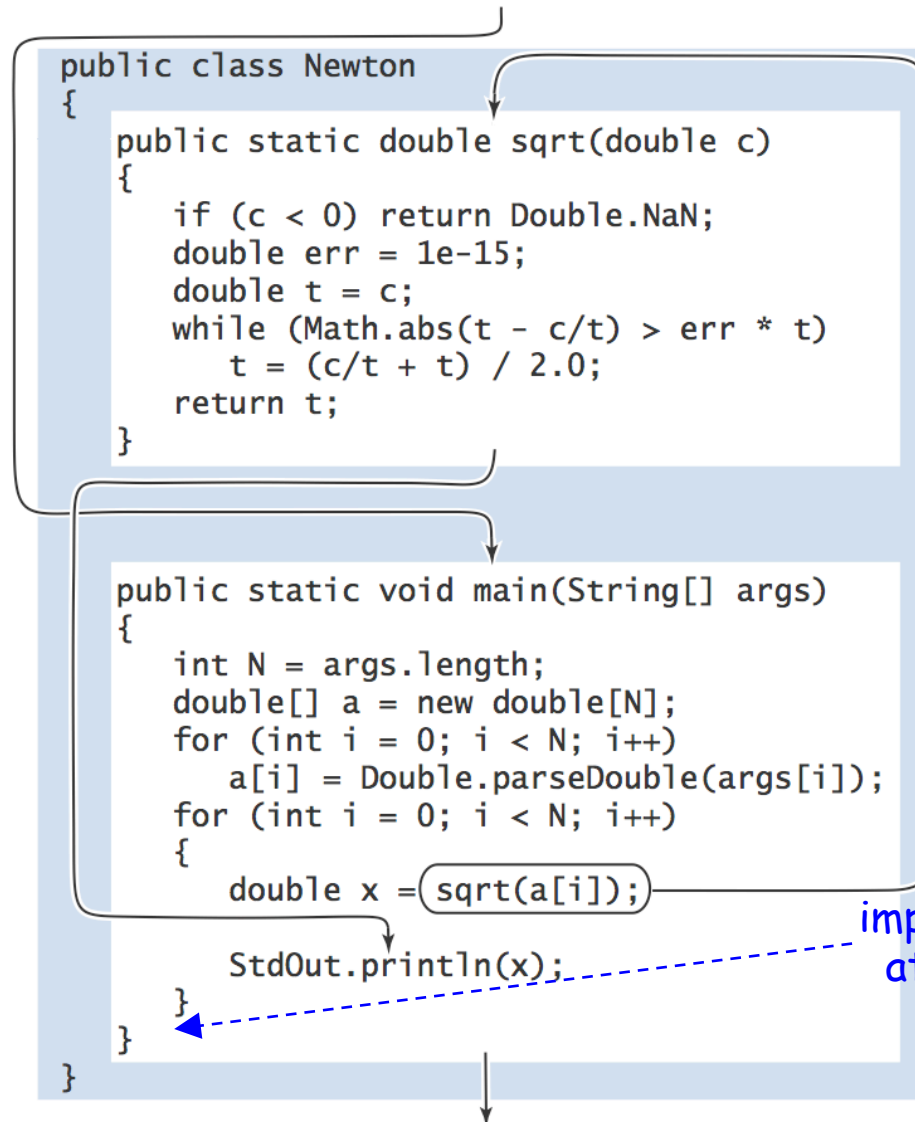

```
}
```

return statement

call on another method

Flow of Control

Functions provide a **new way** to control the flow of execution

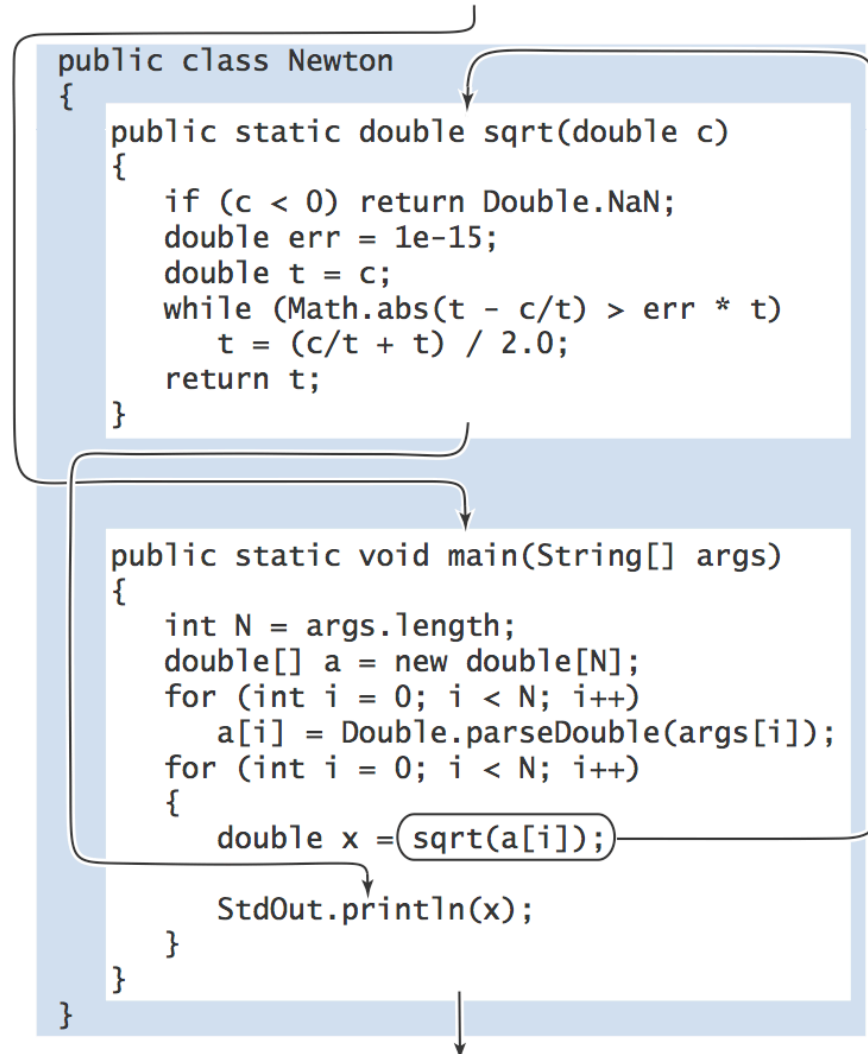

implicit return statement
at end of void function

Flow of Control

What happens when a function is called:

- Control transfers to the function
- Argument variables are assigned the values given in the call
- Function code is executed
- Return value is substituted in place of the function call in the calling code
- Control transfers back to the calling code

Note: This is known as
"pass by value"

Example

- Function to reverse a word
- Apply this word reversal function to reverse a sentence that is entered via command line arguments.

Live coding time

Organizing Your Program

- Functions help you organize your program by breaking it down into a series of steps
 - Each function represents some abstract step or calculation
 - Arguments let you make the function have different behaviors
- **Key Idea:** write something ONCE as a function then reuse it many times

Functions are useful!

- Common adage in programming – DRY principle
- DRY = Don't Repeat Yourself

As opposed to

WET = Write Everything Twice

- Remember, if you are writing too much code that looks similar, it is time to think about a function!

Scope

Scope: the code that can refer to a particular variable

- A variable's scope is the entire code block (any any nested blocks) after its declaration

Simple example:

```
int count = 1;
for (int i = 0; i < 10; i++) {
    count *= 2;
}
// using 'i' here generates
// a compiler error
```

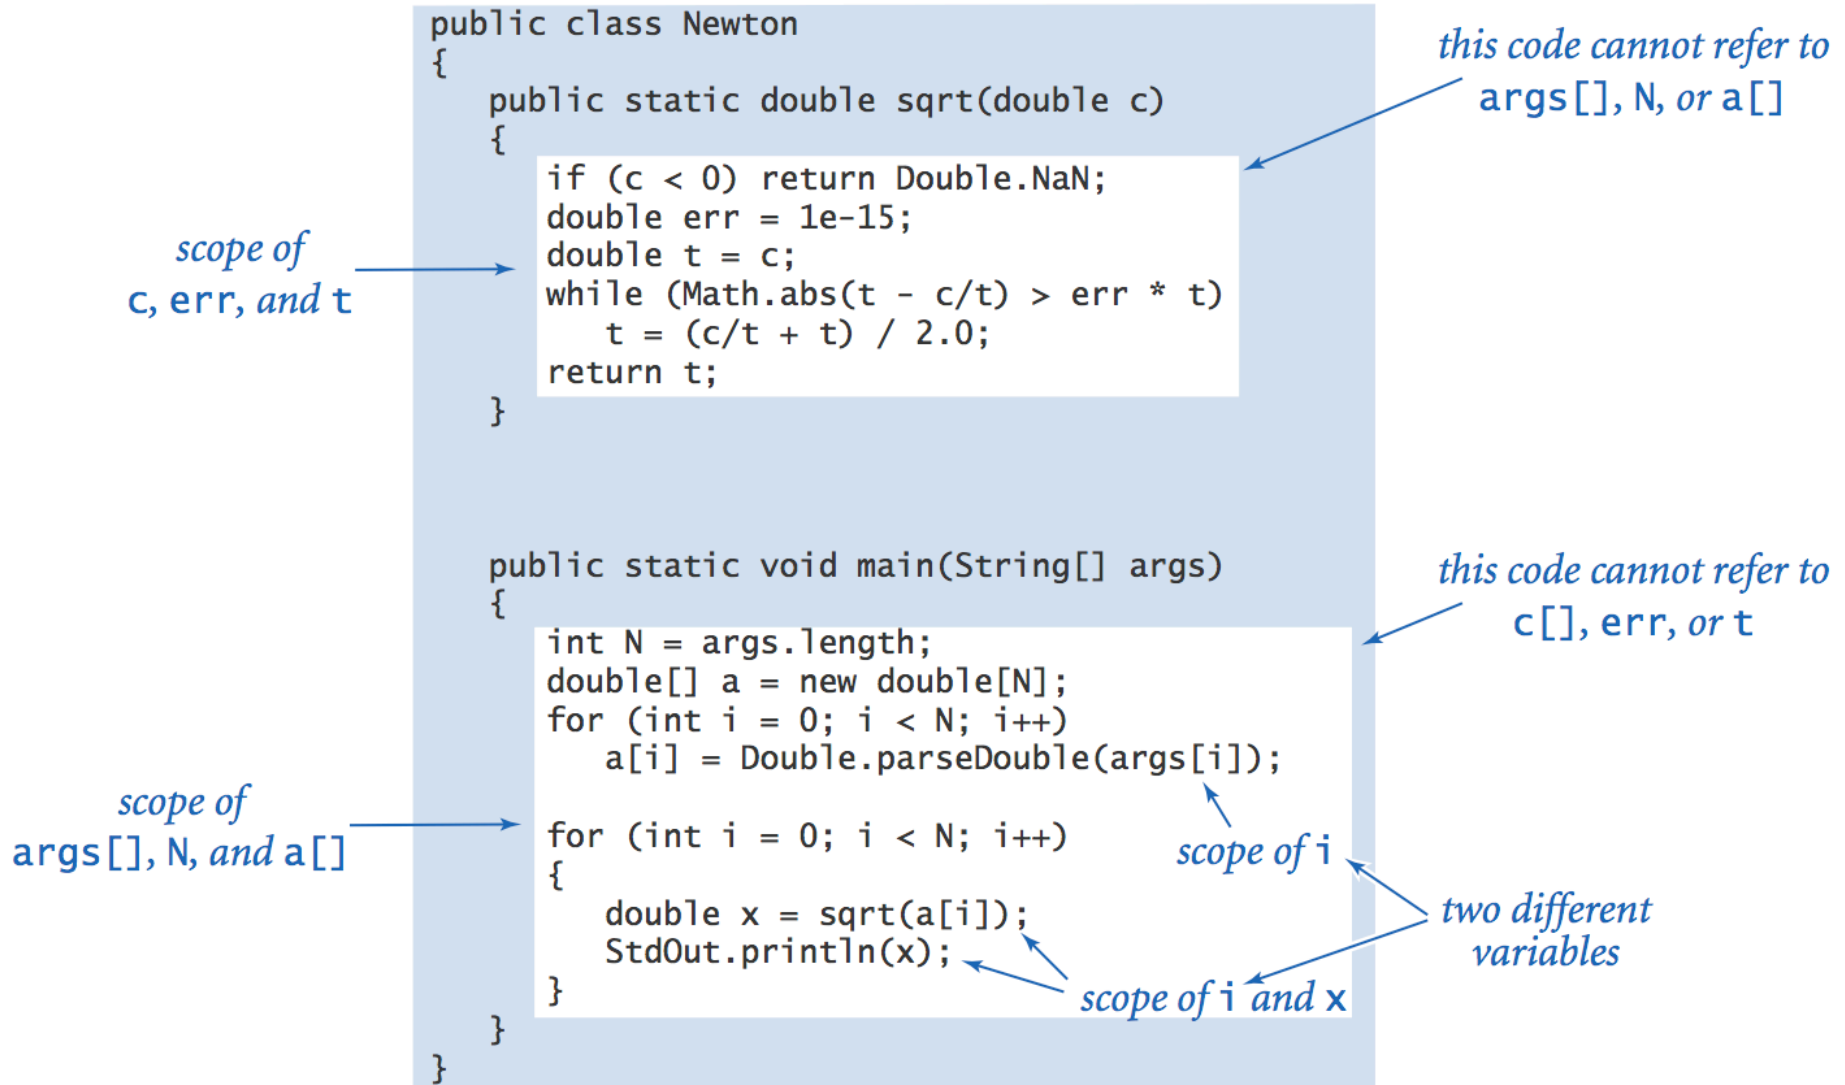

Best practice: declare variables to limit their scope

Function Challenge 1

Q. What happens when you compile and run the following code?

```
public class Cubes1 {  
    public static int cube(int i) {  
        int j = i * i * i;  
        return j;  
    }  
  
    public static void main(String[] args) {  
        int N = Integer.parseInt(args[0]);  
        for (int i = 1; i <= N; i++)  
            System.out.println(i + " " + cube(i));  
    }  
}
```

Scope with Functions

Tracing Functions

```
public class Cubes1 {  
    public static int cube(int i) {  
        int j = i * i * i;  
        return j;  
    }  
  
    public static void main(String[] args) {  
        int N = Integer.parseInt(args[0]);  
        for (int i = 1; i <= N; i++)  
            System.out.println(i + " " + cube(i));  
    }  
}
```

```
% javac Cubes1.java  
% java Cubes1 6  
1 1  
2 8  
3 27  
4 64  
5 125  
6 216
```

Last In First Out (LIFO) Stack of Plates

Method Overloading

- Two or more methods in the same class may also have the same name
- This is called ***method overloading***

*absolute value of an
int value*

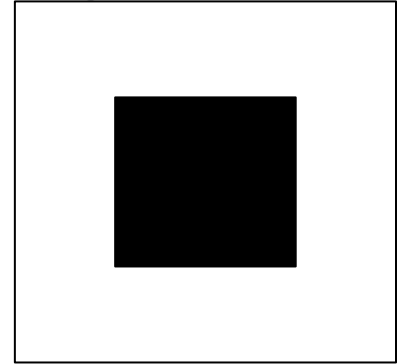

```
public static int abs(int x)
{
    if (x < 0) return -x;
    else      return  x;
}
```

*absolute value of a
double value*

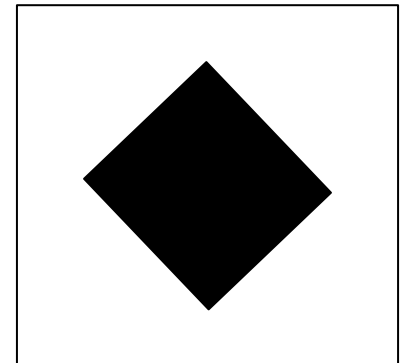

```
public static double abs(double x)
{
    if (x < 0.0) return -x;
    else        return  x;
}
```

Method Overloading

- We need some way to uniquely identify a method
- The name of the method alone isn't enough
 - `PennDraw.square(0.5, 0.5, 0.25)`

- `PennDraw.square(0.5, 0.5, 0.25, 45)`

The methods have the same name,
but do different things!

Method Signature

- A method is uniquely identified by
 - its **name** and
 - **its parameter list** (parameter types and their order)
- This is known as its ***signature***

Examples:

```
static    int min(int a, int b)
static double min(double a, double b)
static  float min(float a, float b)
```

Return Type is Not Enough

- Suppose we attempt to create an overloaded `circle(double x, double y, double r)` method by using different return types:

```
static void    circle(double x, double y, double r) {...}  
  
//returns true if circle is entirely onscreen, false otherwise  
static boolean circle(double x, double y, double r) {...}
```

- This is NOT valid method overloading because the code that calls the function can ignore the return value
`circle(50, 50, 10);`
 - The compiler can't tell which `circle()` method to invoke
 - Just because a method returns a value doesn't mean the calling code has to use it

Too Much of a Good Thing

Automatic type promotion and overloading can sometimes interact in ways that confuse the compiler

For example:

```
// version 1
static void printAverage(int a, double b) {
    ...
}

// version 2
static void printAverage(double a, int b) {
    ...
}
```

Why might this be problematic?

Too Much of a Good Thing

```
static void average(int a, double b) { /*code*/ }  
static void average(double a, int b) { /*code*/ }
```

- Consider if we do this

```
public static void main (String[] args) {  
    ...  
    average(4, 8);  
    ...  
}
```

- The Java compiler can't decide whether to:
 - promote 7 to 7.0 and invoke the first version of `average()`, or
 - promote 5 to 5.0 and invoke the second version
- Take-home lesson: don't be too clever with method overloading

Function Examples

*absolute value of an
int value*

```
public static int abs(int x)
{
    if (x < 0) return -x;
    else      return x;
}
```

overloading

*absolute value of a
double value*

```
public static double abs(double x)
{
    if (x < 0.0) return -x;
    else        return x;
}
```

primality test

```
public static boolean isPrime(int N)
{
    if (N < 2) return false;
    for (int i = 2; i <= N/i; i++)
        if (N % i == 0) return false;
    return true;
}
```

multiple arguments

*hypotenuse of
a right triangle*

```
public static double hypotenuse(double a, double b)
{ return Math.sqrt(a*a + b*b); }
```

Function Challenge 2

Q. What happens when you compile and run the following code?

```
public class Cubes2 {  
    public static int cube(int i) {  
        int i = i * i * i;  
        return i;  
    }  
  
    public static void main(String[] args) {  
        int N = Integer.parseInt(args[0]);  
        for (int i = 1; i <= N; i++)  
            System.out.println(i + " " + cube(i));  
    }  
}
```

Function Challenge 3

Q. What happens when you compile and run the following code?

```
public class Cubes3 {  
    public static int cube(int i) {  
        i = i * i * i;  
    }  
  
    public static void main(String[] args) {  
        int N = Integer.parseInt(args[0]);  
        for (int i = 1; i <= N; i++)  
            System.out.println(i + " " + cube(i));  
    }  
}
```

Function Challenge 4

Q. What happens when you compile and run the following code?

```
public class Cubes4 {  
    public static int cube(int i) {  
        i = i * i * i;  
        return i;  
    }  
  
    public static void main(String[] args) {  
        int N = Integer.parseInt(args[0]);  
        for (int i = 1; i <= N; i++)  
            System.out.println(i + " " + cube(i));  
    }  
}
```

Function Challenge 5

Q. What happens when you compile and run the following code?

```
public class Cubes5 {  
    public static int cube(int i) {  
        return i * i * i;  
    }  
  
    public static void main(String[] args) {  
        int N = Integer.parseInt(args[0]);  
        for (int i = 1; i <= N; i++)  
            System.out.println(i + " " + cube(i));  
    }  
}
```
