Structural Properties of Social Networks

- Nodes with high degree.
- Nodes with high clustering coefficient.
- Nodes with high betweenness centrality (characterizes whether a lot of paths must cross through the node at hand).

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

- Small diameter.
- Many other structural properties...

The Algorithmic Side

- Question 1: If the network contains the structure at hand, how hard is it to find that structure?
- Question 2: Is it substantially easier to find such a structure in a social network than finding such a structure in an arbitrary network (that contains the structure)?
- Potential applications.

Example: Marketing of new product of small budget companies. Find a node with high degree in an online social network and pay that node to add a link to your new product from his online profile. Guarantees that at least that node's immediate friends are exposed to the new product. What Kind of Query Model Should We Use?

Facebook as a model

- As a user of Facebook I am lacking a cenrtal view of the Facebook network.
- ▶ The edges in the network are the connections between friends.
- How hard would it be for me to find a user with lots of friends?
- I can make a Crawl query go to the profile of my friend and check his degree.
- I can make a Jump query by using the Friend's Finder option of Facebook. Typing a random name in Friend's Finder will return a user with that profile (if one exists).

The Model

- At a given user we know his degree and also the identity of his immediate neighbors.
- We can make a Crawl query to move to a specified neighbor of the node at hand.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Or we can make a Jump query to move to a uniformly at random chosen node from the network.

Goals

- In this talk we shall focus on the high degree structure and also the high clustering coefficient structure.
- Definition (approximation of high degree)

Given a parameter $0 \le \alpha \le 1$ and a network *G* with size *n*, we say that a node *v* is an n^{α} approximation if $d^* \le \text{degree}(v) \cdot n^{\alpha}$.

- For $\alpha = 1$, any node works (in a connected network).
- For α = 0, only a node with the highest in the network is a valid answer.
- Answer will depend on type of network considered. Three network categories: arbitrary networks, power law networks, and preferential attachment networks.

High Degree Structure - Arbitrary Connected Network

- Question 1: If the network contains the structure at hand, how hard is it to find that structure?
- Answer- lower bound: Let G be a k-edge connected network, for a fixed k. Let $0 < \beta < 1$. Then $\Omega(n^{\beta})$ Jump and Crawl queries are necessary in order to find a node of degree at least $n^{1-\beta}$.
- Proof idea: In the line-clique graph n^β Jump queries will leave us n^{1-β} distance away from the clique subnetwork part, with constant probability.

Figure: A line-clique network

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

High Degree Structure - Arbitrary Connected Network

- Question 1: If the network contains the structure at hand, how hard is it to find that structure?
- Answer- upper bound: Let G be an arbitrary network. Then there exists an algorithm that with Õ(n^β) Jump and Crawl queries finds a node which gives an approximation ratio of n^{1-β}, w.h.p.
- Algorithm sketch:
 - Let v^* be a maximum degree node (with degree d^*).
 - If $d^* < n^{1-\beta}$ any node will do.
 - Else, with $\tilde{O}(\frac{n}{d^*})$ Jump queries a neighbor of v^* is found.
 - ► Unless such a node has already degree higher than d^{*}/n^{1-β}, by Crawling that node's immediate neighbors we find v^{*}.

• Total number of queries is $\tilde{O}(n^{\beta})$.

High Degree Structure - Power Law Network with n Nodes

- ▶ Degree distribution follows a power law, namely, prob(d) ∝ d^{-γ}, for d = 1, 2, ..., t.
- Question 2: Is it substantially easier to find such a structure in a social network than finding such a structure in an arbitrary network that contains the structure?
- Answer: Yes. Let G be a power Law network with an exponent $\gamma > 2$. Then there exist an algorithm that with $\tilde{O}(n^{\beta})$ Jump and Crawl queries finds a node which gives an approximation of $O(n^{\frac{1}{\gamma}-\frac{\beta}{\gamma-1}})$, w.h.p.

Algorithm sketch: Take Jump $\tilde{O}(n^{\beta})$ Jump queries and return the node with the highest degree between those found. Proof sketch:

- ► The probability of randomly sample a node of degree at least $n^{\left(\frac{\beta}{\gamma-1}\right)}$ is $\theta(n^{-\beta})$ in a power law network with exponent γ .
- ► Highest degree in a power law network is $\theta(n^{\frac{1}{\gamma}})$.

High Degree Structure - Preferential Attachment Network

The PA process creates a network with n nodes in the following way:

- Start with a connected subgraph on *m* nodes.
- In each time step add a new node u and m new links between u and previously added nodes.
- $prob((u, v)) \propto degree(v)$.
- **Expected** degree distribution is a power law of exponent 3.
- ► The realized degree is close to its excepted value for degrees smaller than n¹¹ (implied from a result by Chung and Lu).
- Maximum degree in a realization of the PA process is θ(√n) w.h.p. [Flaxman, Frieze, Fenner].
- Corollary the previous result for power law networks holds for small degrees in the preferential attachment network : with Õ(n^β) queries achieves a O(n^{1/2 − β/2}) approximation.

High Degree Structure - Preferential Attachment Network

We can do better using lazy random walks.

- The Lazy Random Walk (LRW) on the network is mixing fast to the stationary distribution.
- LRW stays put with probability ¹/₂ and with probability ¹/₂ uniformly crawl to a neighbor.
- Question 2: Is it substantially easier to find such a structure in a social network than finding such a structure in an arbitrary network that contains the structure?
- Answer: Yes. Let G be generated using the preferential attachment process. Then, there exists an algorithm that with Õ(n^β) Crawl queries finds a node which gives an approximation of O(n^(¹/₂-β)), w.h.p.

High Degree Structure - Preferential Attachment Network

Algorithm sketch: For $\tilde{O}(n^{\beta})$ times - run the LRW for $\tilde{O}(\log n)$ steps and take the node found at the end of the walk. Finally, return the node with the highest degree between those found. Proof sketch:

- For connected networks the degree distribution is the (unique) stationary distribution of LRW.
- The mixing time of the LRW on the PA network is $\tilde{O}(\log n)$.
- The realized degree distribution is close to its excepted value of $\theta(\frac{1}{d^3})$ for degrees smaller than n^{11} (implied from a result by Chung and Lu).
- ► Therefore the probability of sampling a node of degree d is proportional to d¹/_{d³} = ¹/_{d²}.
- Implies that the probability of sampling a node of degree at least n^β from the degree distribution of a PA network is θ(n^{-β}), for β < 1/11.</p>

Figure: Using the fact that $d^* \le n$ we may compare the achievable rates for all categories.

The Clustering Coefficient Structure

Definition (Clustering Coefficient)

Given a vertex v with degree d, the clustering coefficient (CC) of v is defined as $CC(v) = \frac{\text{number of triangles containing } v}{\binom{d}{2}}$.

Definition (approximation of Clustering Coefficient)

Given a graph on *n* vertices, and a degree value *d*, let v^* be the vertex with the highest *CC* among vertices of degree *d* or more. We say that *v* is a (α, d, ϵ) -approximation to the maximum *CC* if $degree(v) \ge \alpha \cdot d$ and $CC(v^*) \le CC(v) + \epsilon$, for $0 < \alpha \le 1$ and $0 < \epsilon < 1$.

Lower bound: Approximation of $(1, n^{\beta}, 1/2)$ is impossible with $n^{1-\beta}$ queries.

Proof idea: Cannot differentiate between line-star network fro the line-clique subnetwork after taking $n^{1-\beta}$ queries.

Figure: The line-star network

Figure: The line-clique network

▲ロト ▲帰 ト ▲ ヨ ト ▲ ヨ ト つ Q ()

The Clustering Coefficient Structure

Lower bound is tight if we allow logarithmic slack.

- ► There exists an algorithm that with Õ(n^{1-β}) Jump and Crawl queries returns a (¹/_{log n}, n^β, ¹/_{log n}) approximation to the maximum clustering coefficient.
- Proof is quite involved is given in the paper.
- For power law networks where the LRW is mixing fast, e.g. the PA network, we can do substantially better. There exists an algorithm that with Õ(n^{1−2β}) Jump and Crawl queries returns a (¹/_{log n}, n^β, ¹/_{log n}) approximation to the maximum clustering coefficient.
- If β ≥ ¹/₂ need only a poly-logarithmic number of queries for achieving such an approximation.

Future Work

Using sublinear number of Jump and Crawl queries:

- Find two nodes that are diameter distant from each other.
- Find a node with high betweenness centrality measure (measures how many shortest paths are passing through a vertex).

< ロ > < 同 > < E > < E > < E > < 0 < 0</p>

- Other structural properties.
- ► Thank You
